`ctqr-package`*Censored and Truncated Quantile Regression*

Description

Fit quantile regression models to survival data, allowing for right censoring, left truncation, and interval censoring.

Details

Package: `ctqr`
Type: `Package`
Version: `2.2`
Date: `2025-07-23`
License: `GPL-2`

The main function `ctqr` is used for model fitting. Other documented functions are `predict.ctqr`, to obtain prediction from a `ctqr` object, `plot.ctqr`, to plot quantile regression coefficients, and `ctqr.control`, that can be used to set the operational parameters for the estimation algorithm.

ctqr

*Censored and Truncated Quantile Regression***Description**

Fits a quantile regression model to possibly censored and truncated data, e.g., survival data.

Usage

```
ctqr(formula, data, weights, p = 0.5, CDF, control = ctqr.control(), ...)
```

Arguments

formula	an object of class “ formula ”: a symbolic description of the regression model. The response must be a Surv object as returned by Surv (see ‘Details’).
data	an optional data frame containing the variables in the model.
weights	an optional vector of weights to be used in the fitting process. The weights will always be normalized to sum to the sample size. This implies that, for example, using double weights will not halve the standard errors.
p	numerical vector indicating the order of the quantile(s) to be fitted.
CDF	an object of class “pch”, i.e., the result of a call to pchreg . If missing, it will be computed internally with default settings. See ‘Details’.
control	a list of operational parameters for the optimization algorithm, usually passed via ctqr.control .
...	for future arguments.

Details

This function implements the method described in Frumento and Bottai (2017) for censored, truncated quantile regression, and Frumento (2022) for interval-censored quantile regression.

The left side of formula must be of the form `Surv(time, event)` if the data are right-censored, `Surv(time0, time, event)` if the data are right-censored and left-truncated (`time0 < time`, `time0` can be `-Inf`), and `Surv(time1, time2, type = "interval2")` if the data are interval-censored (use `time1 = time2` for exact observations, `time1 = -Inf` or `NA` for left-censored, and `time2 = Inf` or `NA` for right-censored). Using `Surv(time)` is also allowed and indicates that the data are neither censored nor truncated.

The conditional distribution function (CDF) of the response variable represents a nuisance parameter and is estimated preliminarily via [pchreg](#). If missing, `CDF = pchreg(formula)` is used as default. See the “Note” and the documentation of [pchreg](#).

Estimation is carried out using an algorithm for gradient-based optimization. To estimate the asymptotic covariance matrix, standard two-step procedures are used (e.g., Akerberg et al., 2012).

Value

An object of class “ctqr”, which is a list with the following items:

<code>p</code>	the quantile(s) being estimated.
<code>coefficients</code>	a named vector or matrix of quantile regression coefficients.
<code>call</code>	the matched call.
<code>n.it</code>	the number of iterations.
<code>converged</code>	logical. The convergence status.
<code>fitted</code>	the fitted values.
<code>terms</code>	the terms object used.
<code>mf</code>	the model frame used.
<code>covar</code>	the estimated asymptotic covariance matrix.
<code>CDF</code>	the used CDF.

Note that the dimension of all items, except `call`, `terms`, `mf`, and `CDF`, is the same as the dimension of `p`. For example, if `p = c(0.25, 0.5, 0.75)`, `coefficients` and `fitted` will be 3-columns matrices; `n.it` and `converged` will be vectors of 3 elements; and `covar` will be a list of three covariance matrices.

The generic accessor functions `summary`, `plot`, `predict`, `coef`, `terms`, `nobs`, can be used to extract information from the model. The functions `waldtest` (from the package **lmtest**), and `linearHypothesis` (from the package **car**) can be used to perform Wald test, and to test linear restrictions. These functions, however, will only work if `p` is scalar.

Note

NOTE 1. The first-step estimator (the CDF argument) is computed using the `pchreg` function of the **pch** package. To be correctly embedded in `ctqr`, a `pch` object must be constructed using the same observations, in the same order.

If the first-step estimator is biased, and there is censoring or truncation, the estimates of the quantile regression coefficients and their standard errors will also be biased.

If the data are neither censored nor truncated, the CDF does not enter the estimating equation of the model. However, since the first-step estimator is used to compute the starting points, the final estimates may be sensitive to the supplied CDF.

NOTE 2. Right-censoring is a special case of interval censoring, in which exact events are identified by `time2 = time1`, while censored observations have `time2 = Inf`. Note, however, that `ctqr(Surv(time1, time2, type = "interval2") ~ x)` will not be identical to `ctqr(Surv(time = time1, event = (time2 < Inf)) ~ x)`. The estimating equation used for interval-censored data is that described in Frumento (2022), while that used for right-censored data is that of Frumento and Bottai (2017). The two estimating equations are only asymptotically equivalent.

Examples

```
# Using simulated data

# Example 1 - censored data #####

n <- 1000
x1 <- runif(n); x2 <- runif(n) # covariates
t <- runif(n, 0, 1 + x1 + x2) # time variable (e.g., time to death)
c <- runif(n,0,5)             # censoring variable (e.g., end of follow-up)
y <- pmin(t,c)                 # observed variable = min(t,c)
d <- (t <= c)                  # 1 = event (e.g., death), 0 = censored

CDF1 <- pchreg(Surv(y,d) ~ x1 + x2)
model1 <- ctqr(Surv(y,d) ~ x1 + x2, p = 0.5, CDF = CDF1)
model2 <- ctqr(Surv(y,d) ~ x1, p = 0.5, CDF = CDF1)

# model1 is identical to ctqr(Surv(y,d) ~ x1 + x2, p = 0.5)
# model2 is NOT identical to ctqr(Surv(y,d) ~ x1, p = 0.5),
#   which would have default CDF = pchreg(Surv(y,d) ~ x1)

# Example 2 - censored and truncated data #####

n <- 1000
x1 <- runif(n); x2 <- runif(n) # covariates
t <- runif(n, 0, 1 + x1 + x2) # time variable
c <- runif(n,0,5)             # censoring variable
y <- pmin(t,c)                 # observed variable = min(t,c)
d <- (t <= c)                  # 1 = event, 0 = censored

z <- rnorm(n) # truncation variable (e.g., time at enrollment)
w <- which(y > z) # data are only observed when y > z
z <- z[w]; y <- y[w]; d <- d[w]; x1 <- x1[w]; x2 <- x2[w]

# implement various CDFs and choose the model with smallest AIC

CDFs <- list(
```

```

pchreg(Surv(z,y,d) ~ x1 + x2, breaks = 5),
pchreg(Surv(z,y,d) ~ x1 + x2, breaks = 10),
pchreg(Surv(z,y,d) ~ x1 + x2 + x1:x2, breaks = 5),
pchreg(Surv(z,y,d) ~ x1 + x2 + x1^2 + x2^2, breaks = 10)
)

CDF <- CDFs[[which.min(sapply(CDFs, function(obj) AIC(obj)))]
summary(ctqr(Surv(z,y,d) ~ x1 + x2, p = 0.5, CDF = CDF))

# Example 3 - interval-censored data #####
# t is only known to be in the interval (t1,t2) #####

n <- 1000
x1 <- runif(n); x2 <- runif(n)      # covariates
t <- runif(n, 0, 10*(1 + x1 + x2)) # time variable
t1 <- floor(t)                     # lower extreme of the interval
t2 <- ceiling(t)                   # upper extreme of the interval

model <- ctqr(Surv(t1,t2, type = "interval2") ~ x1 + x2, p = 0.5)

```

ctqr.control

Auxiliary Function for Root Search

Description

This functions can be used within a call to `ctqr`, to control the operational parameters of the root search algorithm.

Usage

```
ctqr.control(tol = 1e-06, maxit = 1000, a = 0.5, b = 1.25)
```

Arguments

<code>tol</code>	positive convergence tolerance: the algorithm stops when the maximum absolute change between two consecutive estimates is smaller than <code>tol</code> .
<code>maxit</code>	maximum number of iterations.
<code>a, b</code>	numeric scalar with $0 < a < 1$ and $b > 1$. See ‘Details’.

Details

For a current estimate `beta`, a new estimate is computed as `beta_new = beta + delta*s(beta)`, where `s(beta)` is the current value of the estimating equation and `delta` is a positive multiplier. If `sum(s(beta_new)^2) < sum(s(beta)^2)`, the iteration is accepted and `delta` is multiplied by `b`. Otherwise, `beta_new` is rejected and `delta` is multiplied by `a`. By default, `a = 0.5` and `b = 1.25`. Choosing `a, b` closer to 1 may result in a more accurate estimate, but will require a larger number of iterations.

Value

The function returns its arguments. If some was not correctly specified, it is set to its default and a warning message is returned.

plot.ctqr

Plot Quantile Regression Coefficients

Description

Plots quantile regression coefficients $\beta(p)$ as a function of p , based on a fitted model of class “ctqr”.

Usage

```
## S3 method for class 'ctqr'
plot(x, which = NULL, ask = TRUE, ...)
```

Arguments

x	an object of class “ctqr”.
which	an optional numerical vector indicating which coefficient(s) to plot. If which = NULL, all coefficients are plotted.
ask	logical. If which = NULL and ask = TRUE (the default), you will be asked interactively which coefficients to plot.
...	additional graphical parameters, that can include xlim, ylim, xlab, ylab, col, lwd. See par .

Details

With this command, a plot of $\beta(p)$ versus p is created, provided that at least two quantiles have been estimated. Dashed lines represent 95% confidence intervals, while the horizontal dotted line indicates the zero.

[ctqr](#)

Examples

```
# using simulated data

n <- 1000
x <- runif(n)
t <- 1 + x + rexp(n)
c <- runif(n, 1,10)
y <- pmin(c,t)
d <- (t <= c)

par(mfrow = c(1,2))
plot(ctqr(Surv(y,d) ~ x, p = seq(0.05,0.95,0.05)), ask = FALSE)
```

predict.ctqr

Prediction After Quantile Regression

Description

This function returns predictions for an object of class “ctqr”.

Usage

```
## S3 method for class 'ctqr'
predict(object, newdata, se.fit = FALSE, ...)
```

Arguments

object	a ctqr object.
newdata	optional data frame in which to look for variables with which to predict. It must include all the covariates that enter the quantile regression model. If omitted, the fitted values are used.
se.fit	logical. If TRUE, standard errors of the predictions are also computed.
...	for future methods.

Details

This function produces predicted values obtained by evaluating the regression function at newdata (which defaults to `model.frame(object)`).

Value

If `se = FALSE`, a matrix of fitted values, with rows corresponding to different observations, and one column for each value of `object$p`. If `se = TRUE`, a list with two items:

fit	a matrix of fitted values, as described above.
se.fit	a matrix of estimated standard errors.
